

KBC data solutions

VoidStone

Abstract

Our algorithmic database learns linearly with the amount of shown problems whilst seamlessly integrating AI reliably into the process. The system grows at a constant pace given an exponential growth of the company, having a linearly increasing storage demand but maintains a constant required workforce.

Every time a client contacts the servers concerning a certain problem, a token is made with the client's information and an AI agent condenses the problem into a few keywords and orders it on importance. A solution to the problem is searched within the database. If no such solution is found, a path is created and stored within the token containing every action taken, like clicking a link, contacting a person, etc. Eventually the user logs off or solves the problem. In the first case the token is stored for a reasonable amount of time, the next time the user opens the platform the token resumes the solution path, if another problem is stated another token is made and likewise stored. Eventually the problem is either solved or too complex to be solved. Either way, that information too is stored within the token.

Then the token as a whole is send over to a team of professionals whom look at the solution and checks for errors, inefficiencies and possible duplicate or useless actions. Then another AI agent looks over the validity of the solutions and returns it to the verifying team if the solution might contain errors. Once the problem is certified to be correct, it is put in the databank; a binary search tree who's branches contains keywords. If a keyword is not found a new branch is started containing that keyword at the last known location. This is how the dataset grows with keywords and their corresponding solutions.

At first, many problems will flow in. But eventually most will have been seen and solved. It is a well known statistic that 80% of all problems are caused by 20% of the sources. Thus the amount of unique problems flowing in will drop exponentially. This would perfectly counteract the exponential growth of the company, ensuring an eventual nearly constant stream of problems, though they will get more and more complex and require longer and more intricate solutions.
